

Type	Explanation																																														
<p><b>Intuition</b></p>	<p>Instead of directly integrating to find the areas, we can approximate these areas by drawing shapes underneath the curves and adding the areas of all the shapes together. The shapes we commonly draw are rectangles (known as Riemann Sum) or trapezia (known as trapezium rule). We can then add up all the areas of these shapes individually. Remember, definite integrals represent the exact area under a given curve, so it should make total sense that we can consider the shapes underneath the curve and find their areas instead. The more trapezia/rectangles we draw, the better the answer that we get approximates the actual value of <math>\int_a^b f(x) dx</math>. You will never get the EXACT area but at least it will be more accurate (unless you have a horizontal line with a Riemann sum or diagonal line with trapezium sum then it will be exact)</p>																																														
<p><b>Left Riemann Sum</b></p>	<p>Each rectangle's height is determined by evaluating <math>f(x)</math> at the <b>LEFT</b>-hand endpoint of the subinterval the rectangle lives on i.e. the height (y coordinate) of each rectangles is determined by <b>left</b> endpoint of each <math>x</math> interval for each rectangle shown with the <b>pink point</b></p>  <p>In a table format this looks like:</p> <table border="1" data-bbox="1077 526 1540 649"> <tr> <td>X</td> <td>a</td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td>b</td> </tr> <tr> <td>Y</td> <td>6</td> <td>8</td> <td>10</td> <td>15</td> <td>21</td> <td>24</td> <td>29</td> <td>27</td> <td>23</td> <td>19</td> <td>12</td> <td>9</td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td>3</td> </tr> </table> <p>Area = sum of the areas of all rectangles  <math>= (2 \times 6) + (2 \times 8) + (2 \times 10) + (2 \times 15) + (2 \times 21) + (2 \times 24) + (2 \times 29) + (2 \times 27) + (2 \times 23) + (2 \times 19) + (2 \times 12) + (2 \times 9)</math>  <math>= 2(6+8+10+15+21+24+29+27+23+19+12+9)</math>  <math>= 406</math></p> <p>General formula: <math>\int_a^b f(x) dx = w[y_0 + y_1 + y_2 + y_3 + \dots + y_{n-1}]</math> where <math>w = \frac{b-a}{n} = \frac{b-a}{\text{number of rectangles/strips}} = \frac{b-a}{\text{number of coordinates}-1}</math></p> <p>The formula basically says <math>h[1^{st} y + 2^{nd} y + 3^{rd} y + \dots + (\text{one from last})y]</math></p> <p>What happens when the widths aren't the same? We can't use the formula as the width cannot be found by <math>\frac{b-a}{n}</math> since you will not be dividing the interval evenly. We do manually it by adding all the individual rectangle areas. Notice how we don't use the <math>x</math> values, we use the widths and the <math>y</math> coordinates!</p>  <p>etc</p> <p>Increasing <math>\Rightarrow</math> underestimate and decreasing <math>\Rightarrow</math> overestimate</p>	X	a																				b	Y	6	8	10	15	21	24	29	27	23	19	12	9									3		
X	a																				b																										
Y	6	8	10	15	21	24	29	27	23	19	12	9									3																										
<p><b>Right Riemann Sum</b></p>	<p>Each rectangle's height is determined by evaluating <math>f(x)</math> at the <b>RIGHT</b>-hand endpoint of the subinterval the rectangle lives on i.e. the height (y coordinate) of each rectangles is determined by <b>right</b> endpoint of each <math>x</math> interval for each rectangle, shown with the <b>blue point</b></p>  <p>In a table format this looks like:</p> <table border="1" data-bbox="1029 1355 1540 1489"> <tr> <td>X</td> <td>a</td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td>b</td> </tr> <tr> <td>Y</td> <td>6</td> <td>8</td> <td>10</td> <td>15</td> <td>21</td> <td>24</td> <td>29</td> <td>27</td> <td>23</td> <td>19</td> <td>12</td> <td>9</td> <td>3</td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> <td></td> </tr> </table> <p>Area = sum of the areas of all rectangles  <math>= (2 \times 8) + (2 \times 10) + (2 \times 15) + (2 \times 21) + (2 \times 24) + (2 \times 29) + (2 \times 27) + (2 \times 23) + (2 \times 19) + (2 \times 12) + (2 \times 9) + (2 \times 3)</math>  <math>= 2(8+10+15+21+24+29+27+23+19+12+9+3)</math>  <math>= 400</math></p> <p>General formula: <math>\int_a^b f(x) dx = w[y_1 + y_2 + y_3 + \dots + y_n]</math> where <math>h = \frac{b-a}{n} = \frac{b-a}{\text{number of rectangles/strips}} = \frac{b-a}{\text{number of coordinates}-1}</math></p> <p>The formula basically says <math>h[1^{st} y + 2^{nd} y + 3^{rd} y + \dots + (\text{last})y]</math></p> <p>What happens when the widths aren't the same? We can't use the formula as the width cannot be found by <math>\frac{b-a}{n}</math> since you will not be dividing the interval evenly. We do manually it by adding all the individual rectangle areas. Notice how we don't use the <math>x</math> values, we use the widths and the <math>y</math> coordinates!</p>  <p>etc</p> <p>Increasing <math>\Rightarrow</math> overestimate and decreasing <math>\Rightarrow</math> underestimate</p>	X	a																					b	Y	6	8	10	15	21	24	29	27	23	19	12	9	3									
X	a																					b																									
Y	6	8	10	15	21	24	29	27	23	19	12	9	3																																		

**Midpoint Riemann Sum**

Each rectangle's height is determined by evaluating  $f(x)$  at the **middle** of the subinterval the rectangle lives on i.e. the height (y coordinate) of each rectangles is determined by **middle** of each  $x$  interval for each rectangle, shown with the **purple point**

In a table format this looks like:

X	a																					b	
Y	6	7	8	9	10	12	15	18	21	23	24	27	23	19	15	11	7	3					29

Area = sum of the areas of all rectangles  
 $= (2 \times 7) + (2 \times 9) + (2 \times 12) + (2 \times 15) + (2 \times 18) + (2 \times 21) + (2 \times 24) + (2 \times 27) + (2 \times 23) + (2 \times 19) + (2 \times 15) + (2 \times 11) + (2 \times 7) + (2 \times 3)$   
 $= 2(7+9+12+15+18+21+24+27+23+19+15+11+7+3)$   
 $= 402$

General formula:

Notice how we don't use the  $x$  values, we use the widths and the  $y$  coordinates!

General formula:  $\int_a^b y dx = h [y_1 + y_3 + y_5 + \dots + y_{n-3} + y_{n-1}]$  where  $h = \frac{b-a}{\text{number of rectangles/strips}} = \frac{b-a}{\text{number of coordinates}-1}$

The formula basically says  $h[\text{middle of } 1^{\text{st}} \text{ two } y\text{'s} + \text{middle of } 2^{\text{nd}} \text{ and } 3^{\text{rd}} + \text{middle of } 3^{\text{rd}} \text{ and } 4^{\text{th}} y + \dots + \text{middle of one from last and last } y]$

What happens when the widths aren't the same? We can't use the formula as the width cannot be found by  $\frac{b-a}{n}$  since you will not be dividing the interval evenly. We do manually it by adding all the individual rectangle areas. Notice how we don't use the  $x$  values, we use the widths and the  $y$  coordinates!

X	a								b	etc
Y	$y_0$	$y_{0.5}$	$y_1$	$y_{1.5}$	$y_2$	$y_{2.5}$	$y_3$			

Concave up  $\Rightarrow$  overestimate in total and concave down  $\Rightarrow$  underestimate in total

The midpoint sum is better than trapezium rule below since the errors balance each other out. It Overestimates AND underestimates. The Mid ordinate is more accurate than trapezium rule below, but trapezium rule is more accurate than left and right sums.

**Trapezium Rule**

Now drawing trapezia instead of rectangles

	a								b	
	3	6	8	7	6	2				

Area = sum of the areas of all trapezoids  
 $= \frac{1}{2} \times 5(3+6) + \frac{1}{2} \times 5(6+8) + \frac{1}{2} \times 5(8+7) + \frac{1}{2} \times 5(7+6) + \frac{1}{2} \times 5(6+2)$   
 $= \frac{1}{2} \times 5(3+6+6+8+8+7+7+6+6+2)$   
 $= \frac{1}{2} \times 5[3+2(6)+2(8)+2(7)+2(6)+2]$   
 $= 147.5$

General formula:  $\int_a^b y dx = \frac{h}{2} [y_0 + 2(y_1+y_2+y_3+y_4 + \dots) + y_n]$  where  $h = \frac{b-a}{\text{number of strips}} = \frac{b-a}{\text{number of coordinates}-1}$

The formula basically says  $\frac{1}{2}h[1^{\text{st}} y + 2(\text{middle } y\text{'s}) + \text{last } y]$

What happens when the widths aren't the same? We can't use the formula as the width cannot be found by  $\frac{b-a}{n}$  since you will not be dividing the interval evenly. We do manually it by adding all the individual trapezia areas. Notice how we don't use the  $x$  values, we use the widths and the  $y$  coordinates!

X	a								b	etc
Y	$y_0$	$y_1$	$y_2$	$y_3$	$y_4$	$y_5$				

concave up  $\Rightarrow$  overestimate and concave down  $\Rightarrow$  underestimate
